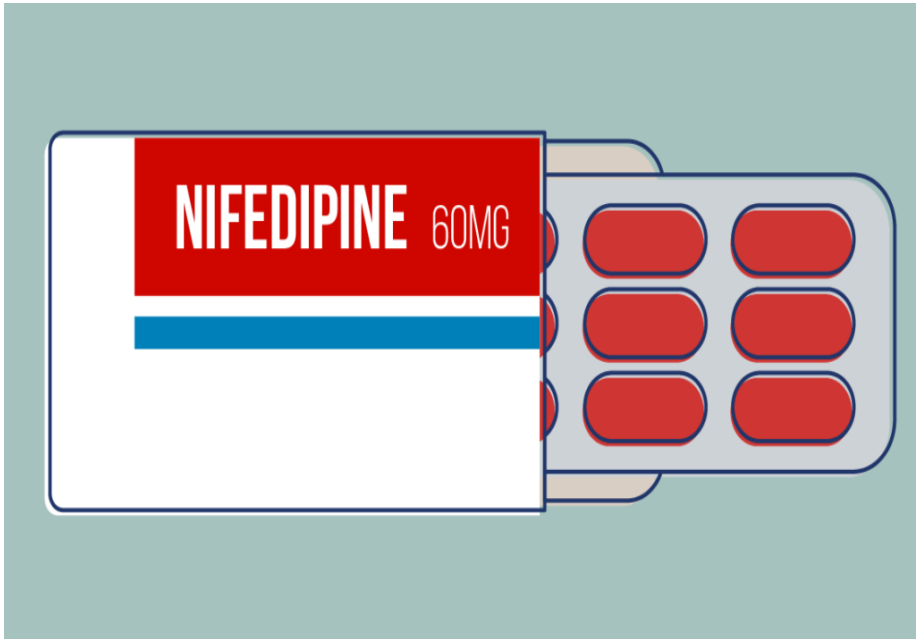
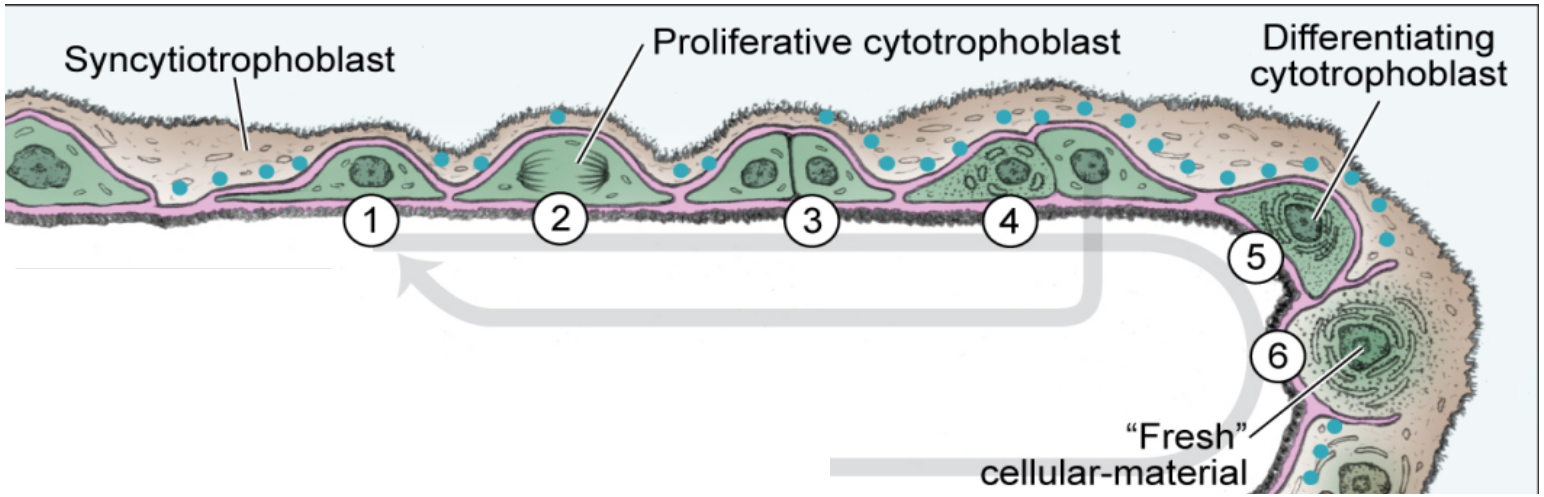
Systemic Vasodilation: the Key to Pregnancy Success



The surface of Healthy Placental Villi Secretes Increasing amounts of PlGF



Kingdom & Drewlo, Blood, 2011

In the normal "high circulating PlGF" state VEGF is displaced over to it's potent VEGFR-2 receptor to stimulate angiogenesis and vaso-relaxation

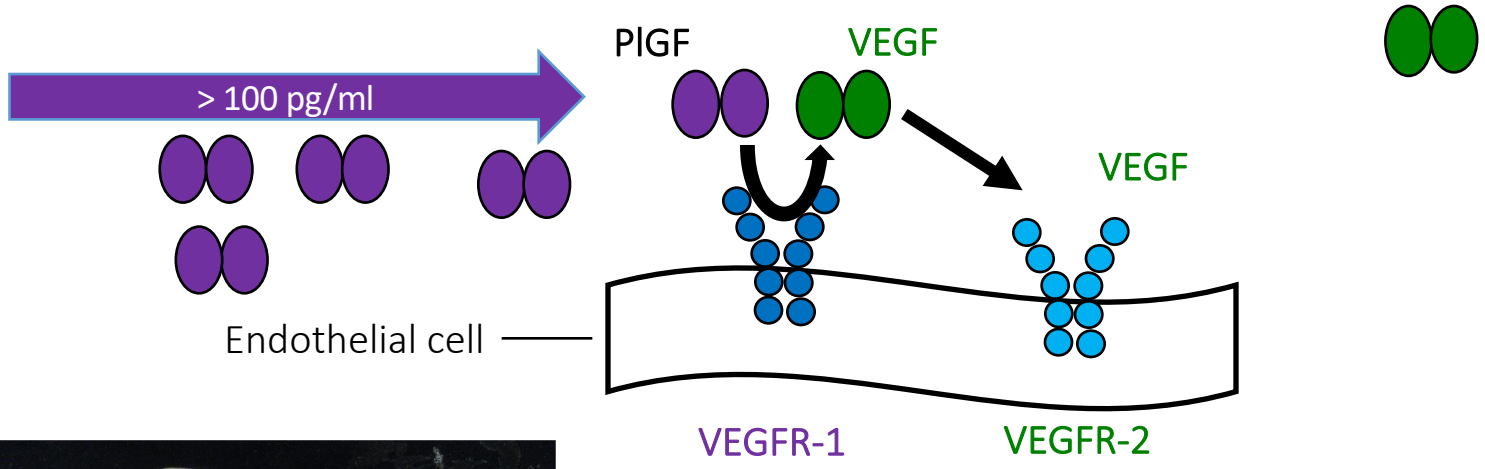


FIGURE 2

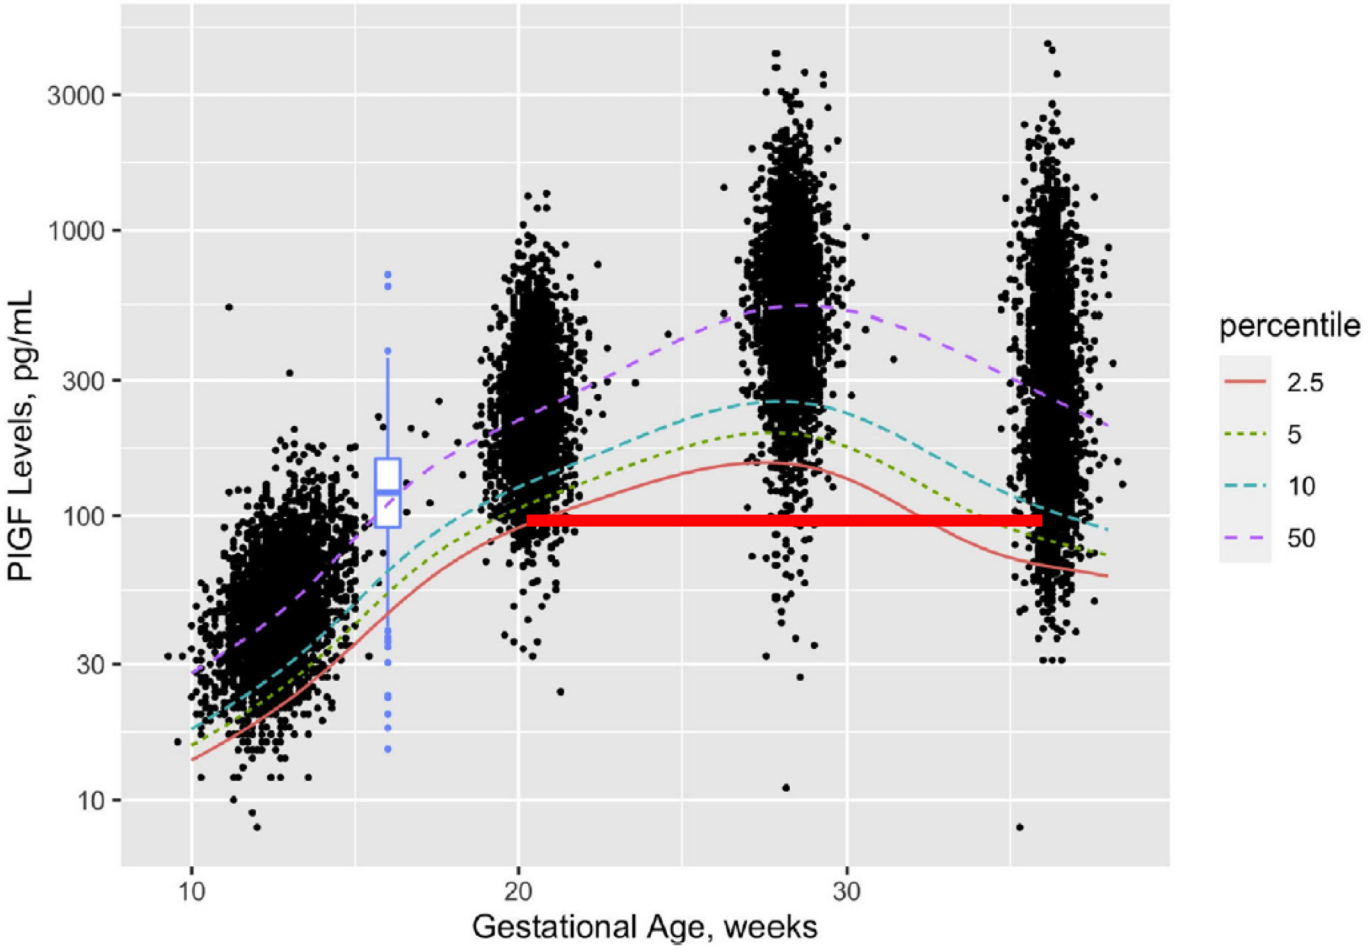
Gestational age-specific distribution of circulating maternal PIGF levels

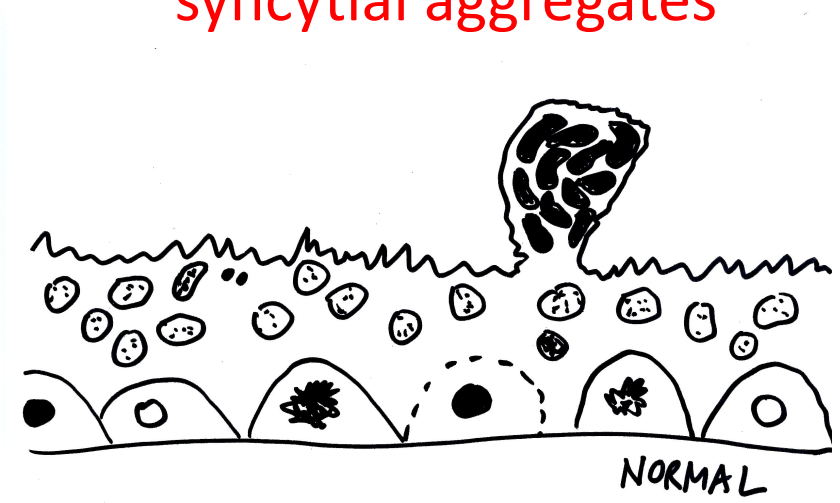


McLaughlin & Kingdom, AJOG 2021 (Sept)

In normal placental development the villi secrete high amounts of PlGF and suppress synthesis and release of sFlt-1 from syncytial aggregates

PlGF ↑

sFlt-1 ↓



In a pathologic "low circulating PlGF" state VEGF remains mostly on it's non-functional VEGFR-1 receptor

Long-Term Primary Aldosteronism Outcome

Brief Review

Should Maternal Hemodynamics Guide Antihypertensive Therapy in Preeclampsia?

Kelsey McLaughlin, Ralph R. Scholten, John C. Kingdom, John S. Floras, John D. Parker

Hypertension in pregnancy impacts ≈10% of all pregnancies.[1] Hypertensive disorders of pregnancy include chronic hypertension, gestational hypertension (new-onset hypertension with blood pressure <140/90 after 20 weeks gestation), or preeclampsia (new-onset hypertension with blood pressure <140/90 after 20 weeks gestation with proteinuria or thrombocytopenia, renal insufficiency, impaired liver function, pulmonary edema, or cerebral/visual symptoms). On the basis of the timing of clinical presentation or delivery, preeclampsia may be further classified into either early-onset preeclampsia (<34 weeks) or late-onset preeclampsia (34 weeks and beyond).

Hypertensive disorders of pregnancy are a leading cause of maternal morbidity and mortality, accounting for 14% of all maternal deaths worldwide.[2] Gestational hypertension is typically benign; however, 46% of women with gestational hypertension will progress to preeclampsia.[3,4] Although less common, preeclampsia is considered a more severe disease that progresses rapidly and is associated with increased risk of subsequently develop early-onset or late-onset preeclampsia exhibit distinct hemodynamic profiles early in pregnancy before the development of clinical hypertension, hemodynamic-guided therapy may improve blood pressure management in women with preeclampsia.[11]

This review will focus specifically on the potential use of maternal hemodynamic-guided therapy for pregnant women with preeclampsia, the more severe hypertensive disorder of pregnancy that has been the subject of intense research in recent years. Hemodynamic-guided therapy for pregnant women with chronic hypertension, gestational hypertension, and preeclampsia superimposed on preexisting hypertension is beyond the scope of this review, as these hypertensive disorders have not been as thoroughly investigated as preeclampsia and there is currently not enough information on maternal hemodynamics in these diseases.

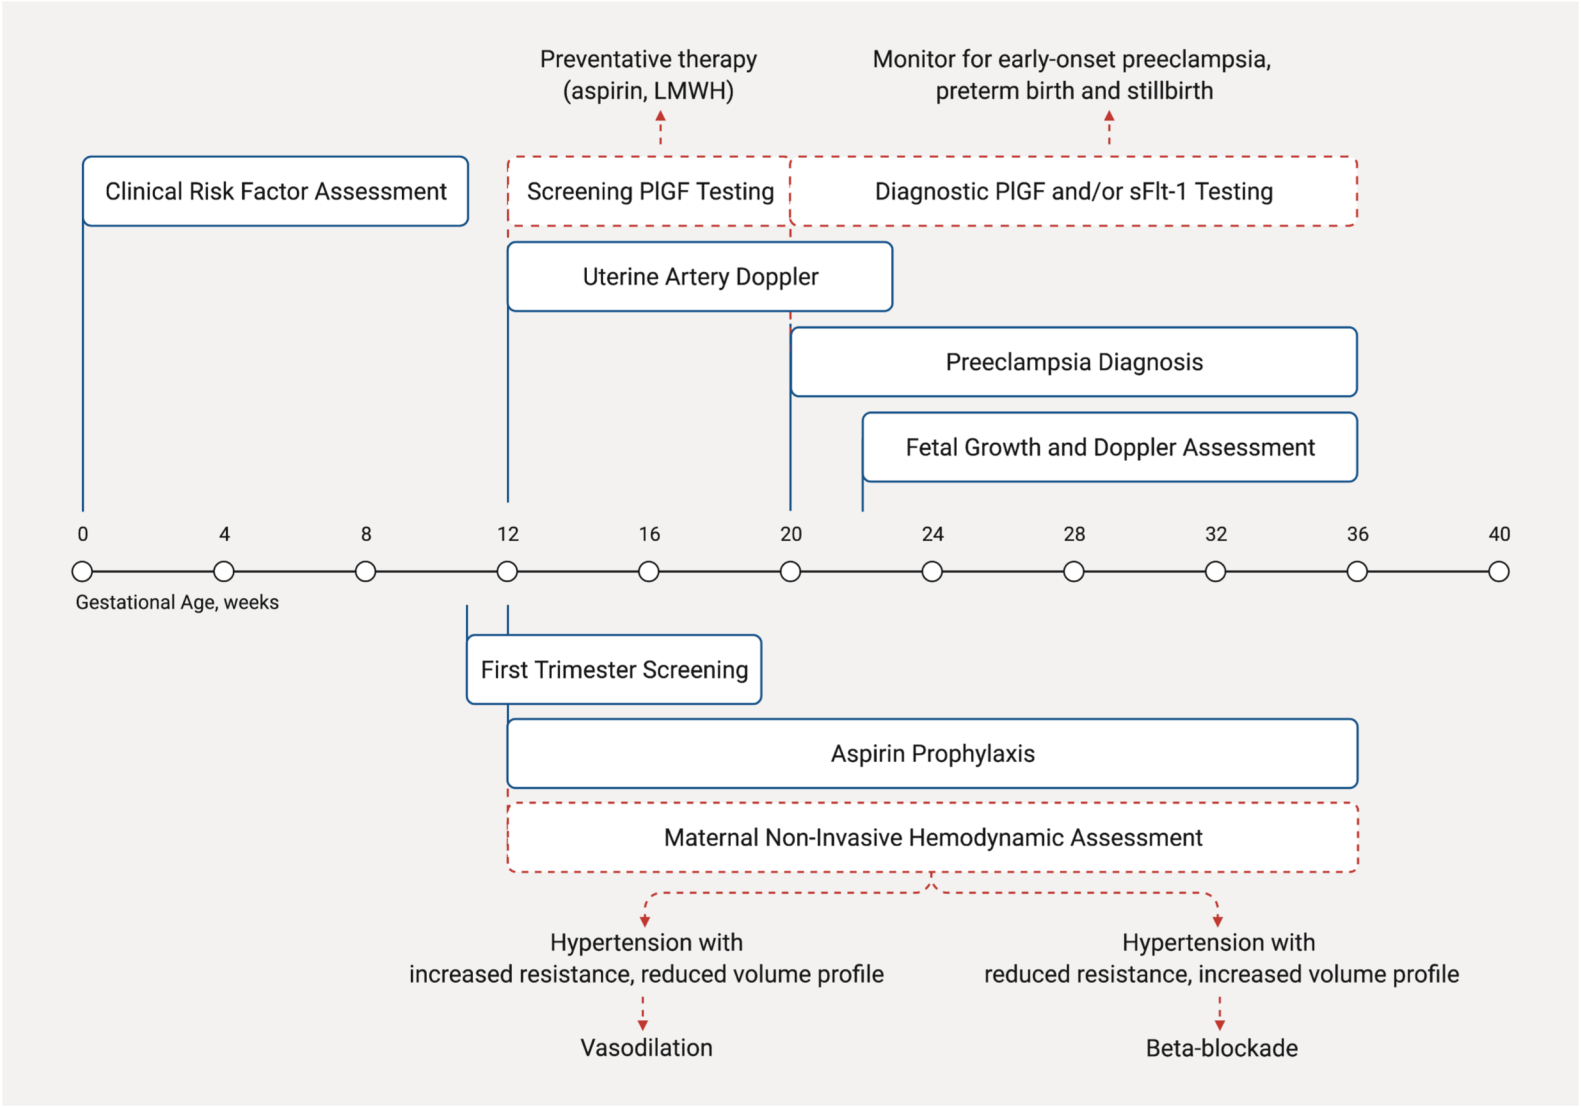
Improving Outcomes for women at risk of preeclampsia: A Multi-Pronged Strategy



THE LANCET

Seminar

Pre-eclampsia

Lucy C Chappell, Catherine A Cluver, John Kingdom, Stephen Tong

Pre-eclampsia is a multisystem pregnancy disorder characterised by variable degrees of placental malperfusion, with release of soluble factors into the circulation. These factors cause maternal vascular endothelial injury, which leads to hypertension and multi-organ injury. The placental disease can cause fetal growth restriction and stillbirth. Pre-eclampsia is a major cause of maternal and perinatal mortality and morbidity, especially in low-income and middle-income countries. Prophylactic low-dose aspirin can reduce the risk of preterm pre-eclampsia, but once pre-eclampsia has been diagnosed there are no curative treatments except for delivery, and no drugs have been shown to influence disease progression. Timing of delivery is planned to optimise fetal and maternal outcomes. Clinical trials have reported diagnostic and prognostic strategies that could improve fetal and maternal outcomes and have evaluated the optimal timing of birth in women with late preterm pre-eclampsia. Ongoing studies are evaluating the efficacy, dose, and timing of aspirin and calcium to prevent pre-eclampsia and are evaluating other drugs to control hypertension or ameliorate disease progression.

Introduction

Pre-eclampsia complicates about 3–5% of all pregnancies and is estimated to cause at least 42 000 maternal deaths annually.[1–3] For every loss related to pre-eclampsia, at least 50–100 women have substantial morbidity.[2,4,5] Low-income and middle-income countries (LMIC) have the highest burden of major complications because of scarce resources and poorer access to adequate obstetric care and family planning services than high-income countries.[6,7]

pressure sustained at ≥90 mm Hg, or both) with proteinuria, or end organ dysfunction after 20 weeks' gestation (panel), or both; appendix p 1 summarises how major international guidelines define pre-eclampsia.[8–12] Organs affected by pre-eclampsia include the brain, causing severe headache, visual disturbances, or eclamptic seizures; the liver, causing epigastric pain or abnormal liver function tests; the kidneys, causing abnormal renal function tests or proteinuria; the haematological system, causing haemolysis, thrombo-
